Declaration

I certify that this work contains no material which has been accepted for the award of any other degree or diploma in my name, in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text. In addition, I certify that no part of this work will, in the future, be used in a submission in my name, for any other degree or diploma in any university or other tertiary institution without the prior approval of the University of Adelaide and where applicable, any partner institution responsible for the joint-award of this degree.

I give consent to this copy of my thesis, when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968.

I also give permission for the digital version of my thesis to be made available on the web, via the University’s digital research repository, the Library Search and also through web search engines, unless permission has been granted by the University to restrict access for a period of time.

Alkhmad Zubaidi
Acknowledgement

I would like to express my sincere gratitude and appreciation to my supervisors, Associate Professor Glenn K. McDonald and Associate Professor Gurjeet Gill. I owe the most gratitude to Associate Professor McDonald, who has given generously of his time and provided excellent supervision throughout my study, especially for his endless patience, understanding and invaluably constructive criticism. I am sincerely thankful to Associate Professor Gill for his invaluable guidance, friendly advice and constructive criticism during the project work and writing. I would also like to sincerely thank my external supervisor, Prof. Mansur Ma’shum from the University of Mataram for his guidance and encouragement during my study, especially field work on Lombok Island Indonesia.

I gratefully acknowledge and thank to all staff and friends of the School of Agriculture, Food and Wine, especially the Agronomy Lab, Waite Institute for their help and friendship. My thanks to Ms. Teresa Fowles for her help in ICP analysis. My special thanks to Dr. Ian Dundas for his help and friendship during my time in Adelaide.

I express my thanks to the Directorate General of Higher Education (DIKTI), Indonesian Department of Education for granting me a scholarship and to the Rector of Mataram University for giving me study leave for conducting this study. My warm thanks also for Dr. Budi Indarsih, Coordinator of DIKTI scholarship at University of Mataram, for her support and guidance on organising my scholarship.

I also wish to express my sincere gratitude to my wife, Ratna, and my children, Annisa, Amalia and Arief for their endless support and patience in every situation. My special thanks also to all my brothers and sisters for their help and moral support during my field experiments in Lombok.
ABSTRACT

Wheat consumption in Indonesia is continuously increasing. Indonesia imports considerable amounts of wheat for domestic consumption and processing and this has increased with economic development. Therefore to lower the high import of wheat grains, Indonesia should have domestic production. Even though Indonesia straddles the equator, the high altitudes in many parts of Indonesia means that wheat could potentially be grown during the dry season as it is more drought tolerant than rice. However, improved adaptation of wheat to tropical environments is needed to achieve this goal.

Lombok Island (8.5°S 116°E) is suggested to be one of the potential areas of wheat growing. The average maximum temperature at the capital city, Mataram (low altitude) is 30-32°C during day time and minimum at 20-23°C at night but this is moderated by elevation in the centre of the island. The lowest temperature during the year is between June and August which also is the dry season. Lombok’s current farming system consists of two rice plantings during the rainy season and a non-rice planting during the dry season. May to September is proposed to be the wheat growing period on Lombok to have the plant flowering during the time of lowest temperatures and coincidently with no or limited rainfall during grain development to avoid grain sprouting in the field before harvested.

In order to investigate the adaptation of wheat on Lombok Island Indonesia, a series of growth chamber and field experiments was conducted. The initial controlled environment experiments at Adelaide University that examined patterns of apical development and seedling growth were done at a continuously high temperature (32/23°C) day/night to imitate temperatures at lowland sites of Lombok Island while in later experiments in which development, growth and yield were studied, the temperature treatments were expanded to 3 temperature regime, 32/23°C, 28/20°C to imitate lowland and highland temperatures of Lombok Island and 25/15°C to represent a temperature more
typical of a wheat producing area in a temperate environment. Field experiments were
done in two consecutive years 2010 and 2011 at 3 different elevation sites on Lombok
Island-Indonesia: Sembalun (1000masl), Narmada (200 masl) and Gunung Sari (10masl) in
2010, and Sembalun, Senaru (500masl) and Lekok (10masl) in 2011. Seeds were sown at
6 sowing times in 2010 and 3 sowing times in 2011. A range of Australian varieties with
different maturities were grown and later two Indonesian varieties were included.

Plant development was rapid under continuously high temperature environment
both under controlled environment experiments and in field experiments with double ridge
occurring 15-30 days after sowing and flowering occurring 40-70 days after sowing in
most varieties. There was good correlation in the rates of development under controlled
environment and field conditions. The differences in flowering time were related to
photoperiod sensitivity and intrinsic earliness among varieties. The results suggested that
early maturing varieties (e.g. Axe) developed very rapidly which may limit their yield
potential.

In the field trials on Lombok, wheat productivity was influenced by elevation and
sowing date. At lowland sites yields were about 1 t/ha or less, whereas when grown at 500
masl elevation or above yields were substantially higher and ranged from 2.2-3.2 t/ha. The
change in yields with elevations was associated with changes in mean temperature: the
change in yield with increasing temperature was -55 g/m²/°C. The optimum sowing time at
higher elevation on Lombok was from mid-May to early June which allowed plants to
flower in the cooler and drier time of the year, and this also allow wheat to fit in with the
current cropping systems. Mid-season varieties that flowered after 65 days were generally
higher yielding than earlier flowering or later flowering varieties. Yield was most strongly
related to grains/m² which emphasised the importance of the timing of the phase of ear and
floret development for sink development in this short season environment.
Growing wheat at 32/23°C greatly reduced wheat yields compared to 28/20°C and 25/15°C due to much more rapid development, lower net photosynthesis rates and lower accumulation of water soluble carbohydrates (WSC). This resulted in reduction in both grain number and kernel weight with yield being relatively more affected by changes in grain number. There was some evidence of genetic variability to heat stress. The differences in yield among varieties was related to differences in photosynthetic rate, stomatal conductance as well as the amount and remobilisation of WSC. Two Indonesian varieties were more tolerant to high temperature than Australian varieties.

The results of this work suggested that it is feasible to grow wheat on Lombok Island at elevations above 500 m. Mid-season varieties that flower after 60-70 days appear to be the most promising pattern of development. There appears to be significant genetic variation in yield to allow further development of improved varieties. Future work should consider adapting wheat into broader potential areas of Indonesia, developing appropriate cropping practices for different altitude and yield potential areas, and introducing or breeding new heat stress tolerant varieties.
