Abstract

Alzheimer's disease (AD) is an increasing global health problem that is expected to affect 65.7 million people by 2030. The major susceptibility gene, the Apolipoprotein (*APOE*) $\epsilon 4$ allele is associated with a 4-fold increased risk for AD if one $\epsilon 4$ allele is present and can advance the age-of-onset of AD by 7-9 years. Carriers of the $\epsilon 4$ allele are also associated with poorer cognitive performance, increased amyloid plaque and neurofibrillary tangle burden and greater levels of neuronal cell death. Previous studies have demonstrated that AD individuals possess elevated levels of genomic instability and an altered lipid and nutritional profile. At present the mechanism by which *APOE* $\epsilon 4$ may accelerate the onset of AD is unknown but may include genomic instability in AD individuals via promoting the intracellular accumulation of the neurotoxic amyloid beta 42 peptide ($A\beta_{42}$) or directly altering the homeostasis of important lipids such as Docosahexaenoic acid (DHA) and cholesterol, which are crucial for optimal brain function. To date, there is limited information regarding the genomic instability profile of *APOE* $\epsilon 4$ carriers and their nutritional status.

The primary aims of the thesis were to investigate the following hypothesis:

- (i) *APOE* $\epsilon 4$ carriers without cognitive impairment have greater levels of chromosomal DNA damage and cell death as measured in human peripheral lymphocytes compared to non- $\epsilon 4$ carriers.
- (ii) *APOE* $\epsilon 4$ carriers without cognitive impairment have an altered lipid and nutritional profile compared to non- $\epsilon 4$ carriers.

The thesis comprised of two distinct studies:

- (i) An *in vitro* study which investigated whether long term supplementation of two fatty acids present in fish oil, i.e. Docosahexaenoic acid (DHA) and Furan Fatty Acids (FFA) can prevent oxidative stress-induced cell death and DNA damage in an astrocytoma cell lines with or without the *APOE* $\epsilon 4$ allele.
- (ii) An *in vivo* study investigating the primary hypothesis that *APOE* $\epsilon 4$ carriers that were not cognitively impaired exhibit greater levels of

chromosomal DNA damage and an altered lipid and nutritional profile compared to non- $\epsilon 4$ carriers.

The Cytokinesis-block micronucleus cytome (CBMN-Cyt) assay was the primary genome instability assay used in both studies, as it is a comprehensive technique that allows chromosomal DNA damage to be measured visually in once-divided cells that are recognised by their binucleate appearance. Examples of chromosomal DNA damage scored include micronuclei (MNi, chromosome breakage and/or loss), nuclear buds (NBUDs, DNA amplification and or removal of DNA repair complexes) and nucleoplasmic bridges (NPBs, DNA misrepair and/or telomere end fusions).

Previous studies have demonstrated that DHA promotes antioxidant defences in the brain, while FFA is emerging as a potential antioxidant and believed to contribute to the benefits of fish oil. The cytotoxic and genotoxic effects of DHA and FFA was investigated in *in vitro* cultures of U87MG (*APOE* $\epsilon 3/\epsilon 3$) and U118MG (*APOE* $\epsilon 2/\epsilon 4$) astrocytoma cell lines with and without a hydrogen peroxide (H_2O_2 , 100 μM) challenge. The *APOE* $\epsilon 4$ cell line was found to be more sensitive to the cytostatic ($P < 0.001$), cytotoxic (i.e., apoptosis, $P < 0.001$) and DNA damaging effects (i.e. MNi, $P < 0.001$; NPBs, $P < 0.001$ and NBUDs, $P < 0.01$) of H_2O_2 when compared to the non- $\epsilon 4$ cell line. DHA at 100 $\mu\text{g}/\text{mL}$ significantly affected cytostasis ($P < 0.05$) and increased DNA damage in the form of NPBs and MNi ($P < 0.05$) in both cell lines, whereas it decreased necrosis ($P = 0.0251$) in the non- $\epsilon 4$ cell line. FFA had no effect on chromosomal DNA damage in both cell lines investigated.

Findings from the *in vivo* study suggest that *APOE* $\epsilon 4$ carriers do not experience significantly different rates of cytostasis, cytotoxicity and/or chromosomal DNA damage (MNi, NPBs and NBUDs) as measured by the CBMN-Cyt assay, when compared to non-*APOE* $\epsilon 4$ carriers after correcting for age and gender. However, there was a trend for increased NPBs and NBUDs in homozygous $\epsilon 4$ carriers compared to non-carriers. Analysis of plasma nutrients and lipids showed no significant differences between $\epsilon 4$ and non- $\epsilon 4$ carriers with the exception of Phosphorus ($P = 0.042$), total plasma cholesterol ($P < 0.0001$) and LDL-cholesterol ($P < 0.0001$) which were higher in *APOE* $\epsilon 4$ carriers.

This study was the first to characterise the CBMN-Cyt assay chromosomal DNA damage profile of *APOE* $\epsilon 4$ carriers. Although no statistically significant differences for any of the cytome biomarkers in our cohort was reported, the limited trend for increased NPBs ($r = 0.118$, $P = 0.06$) suggests the possibility of the loss of systemic genome integrity as measured in surrogate tissues such as lymphocytes but may not adequately explain why *APOE* $\epsilon 4$ carriers are at higher risk of developing AD.

The results of this study are not generalisable to other cohorts with poor lifestyle habits or to non-healthy or older *APOE* $\epsilon 4$ carriers in which the effects of *APOE* $\epsilon 4$ may be more evident (i.e. smokers and obese individuals). In addition, whilst there were no substantial differences in chromosomal DNA damage biomarkers in the form of MNi, NPBs and/or NBUDs in peripheral lymphocytes, DNA damage studies using a large cohort to increase statistical power and other biomarkers such as the buccal micronucleus cytome assay, telomere length and integrity, comet assay and γ H2AX would allow a more complete characterisation of the DNA damage profile of *APOE* $\epsilon 4$ carriers and a more definitive assessment of the role of DNA damage in *APOE* $\epsilon 4$ -related pathology.

Acknowledgements

First of all, I would like to acknowledge my Lord Jesus Christ for his love, grace and mercy, who has filled my life with so many blessings and happiness. My wonderful husband has been tremendously supportive, loving, kind and patient to me throughout my Ph.D. The sacrifices he made for our relationship, not to mention the huge move from Brisbane to Adelaide to be with me and the struggles he had to overcome during his first few years of settling in Adelaide, for that I am truly grateful!! My dearest parents, who have always been there for me, advised me and guided me throughout my life, have been one of my greatest support and role models. I know they truly did their best and I have also reaped the benefits of my Christian upbringing that has helped me tackle my PHD challenges, including the importance of having the right attitude, a willingness to learn, a sense of discipline and being resilient.

I sincerely appreciate the support from my supervisors, Prof. Michael Fenech, Dr Phil Thomas and Prof. Peter Clifton, and for giving me the opportunity to undertake this project with you. Your moral, intellectual and technical support, patience and continual advice and encouragement has helped me to remain focused and perseverant throughout the technical and mental challenges faced in my PHD. A huge thank you to the entire Nutrigenomics laboratory for their great friendship and moral and technical support regarding my laboratory experiments, in particular, Maryam Hor, Carly Moores, Carolyn Salisbury, Theodora Almond, Tina McCarthy, Caroline Bull and Paul Cavuoto for offering their time, expertise and skills in teaching me the various tissue laboratory skills that I have now acquired. Thanks also to Nathan O'Callaghan and Carly Moores for their help in DNA and PCR techniques. Thanks to Maxime Francois and Wayne Leifert for taking the time to demonstrate protein isolation and lipid staining techniques, despite not utilising them during my PHD. Thanks to Chakra Wijesundera for supplying the Furan Fatty Acids at no cost for the *in vitro* study. Thanks to the CSIRO clinic, particularly Julia Weaver, Lindy Lawson and the CSIRO nurses for their help in recruiting, screening, organising and collecting blood samples for the *in vivo* study. A special thank you to all volunteers who enlisted for the *in vivo* study, and generously donated their time, blood and cheek samples for this research. Thanks to Vanessa Russell and her team at CSIRO Analytical and Clinical Chemistry Lab located in

Adelaide for processing the RBC and Lipid samples. Thanks to Waite Analytical Services for analysing the blood mineral plasma samples and the Institute of Medical and Veterinary Sciences (IMVS) pathology laboratories for analysing Vitamin B₁₂ / Folate and homocysteine samples. Thanks to Kylie Lange, for her help with the SPSS software and statistical analysis of my data.

I would also like to thank the University of Adelaide for awarding me with an Australia Postgraduate Award (APA) that has allowed me to undertake my PHD at CSIRO. Thanks to CSIRO Preventative Health Flagship and CSIRO Food and Nutrition for their travel grants and research funding. And to all my dear friends in the Nutrigenomic Lab and those at CSIRO (including Sau Lai, Arnida, Razinah, Nicolas Lepole, Mansi, Kacie, Jeannie), you have truly made this PHD experience enjoyable and a fulfilling one. All in all, I am grateful to everyone who has helped me along this rather long but fulfilling journey.
