Abstract

A global objective of current research is to reduce the cost of manufacturing of titanium parts by improving the efficiency of near net-shape powder metallurgy (PM) technologies. These technologies are considered to be very promising as they eliminate waste and high machining costs. However, the cost of titanium components fabricated with PM remains relatively high due to the significant rate of energy consumption needed for various stages of PM, such as powder processing and sintering. Therefore, more research is needed to reduce the cost of production further, without compromising the mechanical properties and quality of the final product.

The current research is focused on the two latest developments addressing the efficiency problems of current PM: (I) the use of hydrogen as a temporary alloying element in the production of titanium powder, and (II) the application of the Liquid Phase Sintering (LPS) method to enhance the densification of materials. The following aspects of these developments are studied in this thesis: the effect of powder characteristics obtained with the ball milling method and the influence of sintering parameters on the microstructure and mechanical properties of fabricated samples.

The experimental approach includes the following stages: (a) synthesis of TiH_2 from a commercial titanium sponge; (b) particle size reduction through ball milling; and (c) hot press sintering with and without adding a liquid aluminium phase. The TiH₂ powders were investigated for particle size and morphology by laser granulometry and Scanning Electron Microscopy (SEM), and the dehydrogenation kinetic was studied using Differential Scanning Calorimetry, The metallic impurities introduced during ball milling were measured through Inductively Coupled Plasma Optical Emission Spectroscopy (ICP-OES). Sintered specimens were characterised by density using the Archimedes immersion method, and the microstructure and phase composition were examined using SEM Energy Dispersion Spectroscopy (EDS) and X-Ray diffraction (XRD). The hardness of pure titanium specimens was tested by microindentation and the flexural strength of selected LPS specimens was determined using the 3-point bending test. A relationship between the ball milling time and TiH₂ particle size alongside the level of contamination of the Ti powder were established. The influence of the particle size and sintering temperatures, specifically in the bottom range concerned with the energy efficiency, on the densification and dehydrogenation of TiH_2 was studied. The effect of an aluminium phase on the minimum sintering temperatures and quality of the fabricated samples was investigated by varying the concentration of liquid aluminium during hot press sintering.

The outcomes of the current research demonstrated that:

- the size of TiH₂ powder after ball milling greatly increases the density and dehydrogenation of the sintered specimens;
- the dehydrogenation is seen to be delayed by pressure assisted sintering inside a graphite mould;
- ball milling leads to the increased pickup of oxygen on the surface of fine TiH₂ due to the increased specific surface area;
- The aluminium liquid phase is shown to improve the density during pressure assisted sintering at concentrations of 5 to 10 at% aluminium;

- the use of fine particle sizes leads to a faster reaction between the liquid aluminium and titanium and promotes a solid intermetallic phase formation around the aluminium particle site;
- one interesting outcome of the completed research is that the use of a liquid aluminium phase to sinter titanium is shown to improve part density when using pressure-assisted sintering, when compared with previous studies using free sintering.

Overall, it is believed that the conducted study contributes to the understanding and further improvement of PM techniques and demonstrates a significant potential to reduce the fabrication costs of titanium components with ball milling and direct sintering TiH_2 methods. However, a further optimisation of the fabrication parameters and a more comprehensive assessment of mechanical properties are required in order to verify the quality of the fabricated components and for industry to adopt these methods.

Acknowledgements

I would like to express great gratitude for the teaching, guidance, motivation, joy and inspiration given by Jean-François Silvain, Mélanie Lamirand-Majimel, Jean-Louis Bobet, Matthieu Bardet and the members of groups 4 and 1 at the ICMCB, it was a pleasure.

I am also sincerely indebted to Andrei Kotousov for his dedicated support and insightful guidance.

I am grateful to Eric Lebraud, Laëtitia Etienne and Nicolas Penin for their technical assistance, to Alison-Jane Hunter for incredible speed in editing, and I would like to thank Region Aquitaine for its financial support and the DSTO and the MDE group at SES for their support.

I would also like to thank my family for their continuous and immeasurable support.
