1 Introduction 1

1.1 Contextual Statement .............................................. 1

1.2 Lithospheric scale surveys ........................................ 2

1.2.1 Previous EM Studies ........................................... 3

1.3 MT Theory .......................................................... 4

1.3.1 Phase Tensor Theory ........................................... 5

1.3.2 Geomagnetic Depth Sounding ................................ 6

1.4 Factors that affect resistivity ..................................... 7

1.4.1 Basins and Regolith ............................................. 7

1.4.2 Upper Crust ..................................................... 7

1.4.3 Lower Crust .................................................... 7

1.4.4 Sub-continental Lithospheric Mantle ......................... 8

1.5 Geological and Geophysical Background ......................... 9
1.6 Objectives ................................................. 11

2 Magnetotelluric Evidence for Serpentinisation in a Cambrian Subduction Zone beneath the Delamerian Orogen, Southeast Australia 15
   Summary .............................................. 17
   2.1 Introduction ......................................... 18
   2.2 Geological Background .............................. 19
   2.3 Methods ........................................... 23
       2.3.1 MT Method ..................................... 23
       2.3.2 Data Acquisition ............................... 24
       2.3.3 Data processing and pre-inversion analysis .... 25
   2.4 Results ........................................... 27
       2.4.1 2D Inversion ................................... 27
       2.4.2 Model robustness ............................... 30
   2.5 Discussion ......................................... 30
       2.5.1 Interpreting the Conductors .................... 31
       2.5.2 Low resistivity mid-crustal mafic-ultramafic rocks ... 31
       2.5.3 Serpentinisation with magnetite as the conductive mineral ... 33
       2.5.4 Other potential sources of the conductors .......... 35
   2.6 Conclusions ........................................ 36
   Acknowledgments ...................................... 37

3 The Lithospheric Structure of the Transition between the Delamerian and Lachlan Orogens: New Insights from 3D Magnetotelluric Imaging 39
   Summary .............................................. 41
   3.1 Introduction ......................................... 41
   3.2 MT Theory .......................................... 42
   3.3 Method and Results ................................ 44
       3.3.1 Phase tensor ellipses .......................... 45
       3.3.2 Data Inversion ................................ 47
A Appendix

A.1 Model mesh parameters .............................................. 85
A.2 Testing the presence of the conductors .......................... 85
A.3 Dependence of the final model on the starting model ............. 87
A.4 Testing the dependence of the data for the presented model .... 87
A.5 Data fit per site .......................................................... 87

Bibliography 91
LIST OF TABLES

A.1 Table of starting RMS and final RMS for models of different starting resistivities. ........................................ 87
LIST OF FIGURES

1.1 Terrane map of Australia showing the western Archaean to Proterozoic regions, and the eastern Palaeozoic Tasmanides. ........................................ 9

1.2 Overview map of MT site locations used in each chapter. .................... 13

2.1 Cartoon showing geological evolution of western Victoria. 1) 830 Ma on- set of continental rifting. 2) By 520 Ma a thick passive margin sequence has accumulated. 3) 515-500 Ma initiation of Andean subduction. 4) Cambrian architecture still in place today from seismic reflection data. 20

2.2 Simplified geological map showing basins and cover sequences. .......... 21

2.3 Geology of the survey region with post-Palaeozoic cover removed, and locations of serpentinite outlined. ................................................. 23

2.4 Total magnetic intensity with phase tensor ellipses for 0.1 s, 1 s, 10 s and 50 s. ................................................................. 26

2.5 Rose plots for periods ranging from 0.0064 to 82 s showing the geo- electric strike direction. ......................................................... 27

2.6 a) Occam2D smooth model resulting from inversion of all data from the 68 stations of the Southern Delamerian transect. b) Reflection seismic with fault interpretations overlain. c) Geological interpretation based on potential field forward modelling along the transect. ................. 28

2.7 Plots of apparent resistivity and phase for stations SD01, SD27, DB31A and DB35A along the MT transect. ................................. 29

2.8 Electrical conductivity of rocks from VIMP drill holes. Serpentinised rocks show decreased electrical resistivity compared to regional values. 34

2.9 Photograph of a thin section from the Hummocks Serpentinite. Black grains are magnetite grown in the exsolution lamellae of large relic pyroxene grains replaced by chrysotile. ........................................ 35
3.1 MT site locations with tectonic boundaries for the western Victoria MT transects and arrays. 43
3.3 Phase tensor ellipse pseudosections for the measured and modelled responses of the ModEM 3D inversion. 46
3.4 Phase tensor ellipses at a period of 100 s, overlaying total magnetic intensity data. 47
3.5 RMS values from the 3D inversion for sites with an RMS larger than 2.5. 48
3.6 Resistivity depth slices from 3D model at 20, 40, 60 and 100 km with P-wave velocity slices from the Wombat model for the same depths. 49
3.7 Vertical slices taken from the ModEM 3D Model. YF=Yarramyljup Fault, MF=Moyston Fault, AF=Avoca Fault, HF=Heathcote Fault, GSZ=Grampians-Stavely Zone. 51
3.8 2D inversion of MT data from the Southern Delamerian, Delamerian-Lachlan Transition and Bendigo West transects. Fluid pathways and low-resistivity zones are highlighted. 52
3.9 2D WinGLink model overlying the 3D ModEM model at 10 km depth (top) and 37 km depth (bottom). 55
3.10 a) Gravity data with faults overlain. b) TMI data with faults overlain. c) 1 km resistivity depth slice from 3D inversion. d) 37 km resistivity depth slice from 3D inversion. e) Moho depths from the AusMoho model. 57
4.1 Station locations in the Ikara-Flinders Ranges and the Curnamonna Province over topography. 65
4.2 Estimates of depth of MT signal penetration using a Niblett-Bostick transformation. 66
4.3 Phase tensor ellipses over TMI map for a period of 100, 1000 and 7000 s. 67
4.4 Phase tensor ellipses showing the 3D inversion model fit for 100, 500, 1000 and 4000 s. 69
4.5 Resistivity depth slices at 1, 10, 20, 30, 60 and 110 km with earthquakes and diamondiferous kimberlite locations shown. 70
4.6 The Flinders Conductivity Anomaly revisited, at depths of 10 and 30 km, with induction vectors at 100 s and 1000 s respectively. 71
4.7 Total magnetic intensity, bouguer gravity and resistivity for the Curnamonna Province. 72
4.8 Total magnetic intensity, bouguer gravity and resistivity for the Nackara Arc with macrofaults overlain. 75
5.1 Comparison of the Ikara-Flinders Ranges/Curnamona Province 3D inversion (Chapter 4; top) and the western Victoria 3D inversion (Chapter 3; bottom), on the same colour scale for 10, 30 and 60 km. .......................... 80

5.2 Overview map of MT sites locations with regions suggested for future directions highlighted. .................................................. 83

A.1 Inversion results using the same modelling parameters as the presented model, but with the dataset of 74 stations divided into two subsets containing half of the total sites, to test the dependence of the model features on the data. .................................................. 86

A.2 Vertical slices of the final resistivity model taken at the locations shown on the corresponding map. ...................................... 88

A.3 RMS values for each MT site from the final 3D model. Sites with an RMS larger than 2 are shown for: the overall RMS; for each component of the impedance tensor; and for each component of the tipper. ........ 89
Electrical Resistivity Structure of the Southeast Australian Lithosphere

by Kate Robertson

In its ability to retain signatures of tectonic events that enrich or deplete its fertilization state, the lithosphere holds the key to the tectonic evolution and history of Earth. Dewatering of the subducting slab leads to released fluids and induced melt which act to fertilize the overlying mantle in incompatible elements such as hydrogen. Conversely, rifting events lead to partial melting with fertile elements entering the melt, leaving behind a depleted lithosphere. Signatures such as these can remain in the lithosphere for hundreds of millions of years in the absence of further high temperature/melt events.

Magnetotellurics (MT) is a passive geophysical tool that images the physical property of electrical resistivity and is capable of penetrating the entire lithosphere. MT is highly sensitive to minor interconnected conducting mineralogy and fluids, and thus is ideal for distinguishing between lithosphere of different degrees of enrichment. Additionally, the sensitivity to these minor phases means that fossil fluid pathways associated with the ascent of mineralising fluids and metals are detectable with MT. This is the cornerstone on which one of the main directions of the UNCOVER (Australian Academy of Science, 2012) initiative is based on- increasing the detectable signature of ore deposits by imaging the underlying fluid pathways and lateral dispersion of deposits.

With these capabilities in mind, MT surveys were undertaken across western Victoria, Australia and the Ikara-Flinders Ranges and Curnamona Province in South Australia, Australia. The collection, processing and modelling of new MT sites were conducted for this thesis, with many other existing MT sites utilised to expand the dataset.

In Chapter 2, 74 broadband (period of 0.001-2000 s) MT sites along the 1.2-5 km spaced east-west Southern Delamerian transect were processed, modelled and interpreted across western Victoria. The crust beneath the Delamerian Orogen has a heterogeneous resistivity structure, with low-resistivity fossil-fluid pathways stemming from Moho depths, intersecting an otherwise resistive upper crust. Serpentinite with interconnected magnetite is known to occur within the vicinity of the survey region, and conductivity measurements of hand samples indicate substantially lower resistivities for the serpentinised rocks, leading to the interpretation that serpentinite contributed to the low resistivity zones.
Chapter 3 expands on the Southern Delamerian transect of Chapter 2 by modelling the transect using a 3D inversion code, along with four other pre-existing datasets which, when combined, create a 500 km continuous east-west transect. Importantly, this transect traverses the transitional zone between the Delamerian and Lachlan Orogens. The elusive boundary between these Orogens has most recently been interpreted as a gradual boundary within the Stawell Zone. Results from modelling show that the lower crust and shallow upper mantle of the Delamerian Orogen are at least an order of magnitude more resistive than the adjacent Lachlan Orogen. If the location of this sharp gradient in resistivity is chosen as the Delamerian-Lachlan transition, then the boundary occurs about 20 km to the east of the Moyston Fault in a NNW-SSE orientation, in reasonable agreement with seismologically and geochemically determined boundaries.

Finally, Chapter 4 involved the collection of the first set of AusLAMP measurements across an array of 50 km spaced long-period (2-17,000 s) MT sites across the Ikara-Flinders Ranges and Curnamona Province in South Australia. This longer-period dataset was capable of imaging the entire lithosphere, and resulted in the imaging of a surprisingly low resistivity crust for the Palaeo-Mesoproterozoic Curnamona Province, indicating either a long-lived retention of enrichment from the Olarian Orogeny (over 1.5 Ga), a more widespread reworking of the province from the Delamerian Orogeny (540 Ma), or another unrelated more recent enrichment event. The Broken Hill Domain remains largely resistive, indicating that enrichment events associated with the emplacement of the word-class Broken Hill deposit may have been erased during a high temperature or melt event. Further, two conductivity anomalies were identified in the Nackara Arc of the Ikara-Flinders Ranges, and when combined with the Curnamona Conductor, can explain the phenomenon of induction vectors across eastern South Australia all pointing toward an anomalous zone spanning the Ikara-Flinders Ranges north to south in an arcuate fashion, which had previously been interpreted as one single continuous conductivity anomaly, the Flinders Conductivity Anomaly. Coincidence of the Nackara Arc Conductors with locations of discovered kimberlites give evidence for zones of lithospheric weakness, with pathways where CO$_2$-rich kimberlitic melts may have deposited graphite on ascent.
STATEMENT OF ORIGINALITY

I certify that this work contains no material which has been accepted for the award of any other degree or diploma in my name in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text. In addition, I certify that no part of this work will, in the future, be used in a submission in my name for any other degree or diploma in any university or other tertiary institution without the prior approval of the University of Adelaide and where applicable, any partner institution responsible for the joint award of this degree.

I give consent to this copy of my thesis when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968.

Thankyou to my supervisors Graham Heinson and Stephan Thiel for inspiring and supporting me through my research so far. Thankyou for providing me with endless opportunities to attend conferences, go on fieldwork and for creating a positive research group. I am very grateful to David Taylor of the Victorian Geological Survey, your passion for your work is contagious, and I feel privileged to share in your boundless knowledge of the geology of Victoria. The lambs also thank you for your comments that prompted my vegetarianism.

Thankyou to Goran for keeping the MT instruments in tip-top shape and always being so happy and friendly. To the PhD group, I have truly enjoyed the years spent with you all. Sebastian, Paul and Alison- thank you for your friendship, donut-eating competitions and ultra-marathon running company. Thanks to the many people who have helped to collect my field data on many field trips, it is on these trips that I have forged memories that will last a lifetime- from flying over the Ikara-Flinders Ranges in a helicopter to digging holes in 40-plus degree heat!

Thankyou to my partner Bill, for your constant love and support and your advice on creating a work-life balance- advice which played a large part in my ability to complete my PhD with such a positive mindset. Thankyou to my parents, who have always encouraged and believed in me throughout my entire education and for all the thoughtful things you have done for me when Uni became stressful at times. To my sisters- there are no better friends than both of you. I am truly grateful for how close we all are as a family. I thank my friends for their love and friendship, and their understanding for all of the times when I chose study over them.

It is not possible to thank everyone here who played a part in this journey, but I hope I have shown you my gratitude over the years and I look forward to continuing my geophysical journey with you all.
