DOCTORAL THESIS

**An Integrative Analysis of the
Human Placental Transcriptome**

Author:

Sam BUCKBERRY

Primary Supervisor:

Professor Claire ROBERTS

*A thesis submitted in fulfilment of the requirements
for the degree of Doctor of Philosophy*

in the

School of Paediatrics and Reproductive Health
Discipline of Obstetrics and Gynaecology

July 2015

Declaration of Authorship

I certify that this work contains no material which has been accepted for the award of any other degree or diploma in my name, in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text. In addition, I certify that no part of this work will, in the future, be used in a submission in my name, for any other degree or diploma in any university or other tertiary institution without the prior approval of the University of Adelaide and where applicable, any partner institution responsible for the joint-award of this degree.

I give consent to this copy of my thesis when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968.

The author acknowledges that copyright of published works contained within this thesis resides with the copyright holder(s) of those works.

I also give permission for the digital version of my thesis to be made available on the web, via the University's digital research repository, the Library Search and also through web search engines, unless permission has been granted by the University to restrict access for a period of time.

Doctor of Philosophy

An Integrative Analysis of the Human Placental Transcriptome

by Sam BUCKBERRY

Pregnancy outcome is inextricably linked to placental development, which is strictly regulated both temporally and spatially by mechanisms that are only partially understood. Although the placenta is absolutely indispensable for fetal development *in utero*, it remains the least understood human tissue. Although the placenta is a shared organ between the mother and fetus, it is of embryonic origin, and therefore its development is largely regulated by the fetal genome.

This overall goal of this research was to investigate three key aspects of human placental gene regulation: (1) The effect of genomic imprinting on gene regulation, (2) the differences in placental gene expression between the sexes, and (3) the co-expression relationships that exist between genes on a transcriptome scale.

Firstly, this research identified a window of epigenetic imprinting plasticity for the long non-coding RNA *H19*, which is heavily implicated in placental development and function. These results suggested that variation in *H19* imprinting may contribute to early programming of placental phenotype and highlighted the need for quantitative and robust methodologies to further elucidate the role of imprinted genes in normal and pathological placental development.

Secondly, by conducting a transcriptome-scale meta-analysis of sex-biased gene expression, this research revealed that 140 genes are differentially expressed between male and female placentae. A majority of these genes are autosomal, many of which are involved in high-level regulatory processes such as gene transcription, cell growth and proliferation and hormonal function. Of particular interest, all genes in the *LHB-CGB* cluster were expressed more highly in female placentas, which includes genes involved in placental development, the maintenance of

pregnancy and maternal immune tolerance of the conceptus. These results demonstrated that sex-biased gene expression in the normal human placenta occurs across the genome and includes genes that are central to growth, development and the maintenance of pregnancy.

Thirdly, by undertaking a comprehensive analysis of human placental gene co-expression using RNA sequencing and the integration of five human and one mouse transcriptome dataset, this research identified clusters of correlated genes, whose patterns of co-expression are highly preserved across human gestation and between human and mouse, subsequently revealing highly conserved molecular networks involved in placental development. Furthermore, by reducing the complexity of the placental transcriptome by summarizing co-expressed genes, this work identified a group of co-expressed genes implicated in preeclampsia and also outlines a novel method for identifying for non-invasive biomarkers of placental development.

In summary, each aspect of this PhD research has provided new insights into how gene expression is regulated in the human placenta and has revealed previously unappreciated aspects of the placental transcriptional landscape.

Acknowledgements

Science is a collaborative effort and the work presented herein is no exception. I would like to express my sincere gratitude to Claire Roberts and Tina Bianco-Miotto, whose expertise, understanding, and patience, added considerably to my PhD experience. I appreciate and respect their vast knowledge and skill in many areas of reproductive and molecular biology, and am deeply thankful for their assistance in writing up the work presented in this thesis. I would also like to thank the other members of my supervisory committee, Stephen Bent for providing guidance and insight regarding bioinformatics analyses and Gus Dekker for expert advice and assistance regarding the clinical aspects of this research project. I also extend my sincere thanks to Hannah Brown for providing scientific guidance.

I would like to acknowledge Shalem Leemaqz, Dan Kortschak, Jessica Laurence, Prabha Andraweera and Amanda Hight for participating in discussions of this work, Dylan McCullough for laboratory technical support, Liying Yan, Ann Meyer and Matthew Poulin of EpigenDx for their pyrosequencing technical assistance, Joel Geoghegan at the Australian Cancer Research Foundation Cancer Genomics Facility for RNA sequencing support and Kartik Shankar for providing raw RNA sequencing data for validation purposes. I am grateful for the valuable and independent mentoring support from Jozef Gecz, and thank Lisa Martin for assisting with proof reading and copy editing. I would also like to acknowledge the other post-graduate students in the CTR lab; Zimin Zhuang, Fleur Spronk, Benjamin Mayne, Rebecca Wilson, Sultana Khoda, Alison Leviton and Ang Zhou.

I recognise that this research would not have been possible without the financial assistance I have received, and am thankful for the Australian Postgraduate Award from the Australian Government Department for Education and Training, and generous PhD top-up scholarships from the Channel 7 Children's research foundation and Healthy Development Adelaide, and the National Health and Medical Research Council (NHMRC). Support for traveling to conferences was generously provided by The Robinson Research Institute and the Society of Reproductive Biology. Funding for this research was provided by NHMRC through project grants (APP1059120 and APP565320) and a NHMRC Senior Research Fellowship awarded to Claire Roberts (APP1020749).

Finally, I would like to thank my family for all their encouragement during my candidature, and I want to extend a special thank you to my wife Kylie for all her understanding, love and support throughout my undergraduate and postgraduate training.
