Abstract

This study was aimed at determining the expression and activity of polyphenoloxidase (PPO) during apricot fruit development together with the biochemical characteristics of the enzyme extract at different development stages. Biochemical factors considered include substrate, pH, NaCl level, inhibitor type, high temperature inactivation and sulphur dioxide level.

Changes in apricot (*Prunus armeniaca* L., cv. 'Moorpark') polyphenoloxidase (PPO) were measured during fruit development from a few days after full bloom until over-ripe at 92 days after full bloom. Cold ground samples in McIlvaine's buffer were analysed for PPO activity over a range of pH (5.0, 6.0, 6.8 and 7.2); for response to intact fruit sample pre-heating (25, 35, 45, 55 and 65 °C); for sulphite and NaCl inhibition (0.2, 0.5, 2 and 5mM) and other inhibitors (SHAM 0.2mM, cinnamic acid 2.5mM and tropolone 0.5mM). PPO activity was measured at 25°C using a Clark-type oxygen electrode with 4-methyl catechol (20mM) as substrate.

As fruit ripened PPO activity increased under all conditions tested. The increase in activity was not even with fruit development. Three common peaks of PPO activity occurred at ages 22-29 days, 57 days and for fully-ripe fruit at 85-92 days.

Optimum pH was found to be 6.8 with a wide range for all ages of fruit. PPO activity tended to be higher for more mature fruit at a higher pH of 7.2 to 8.0, whereas activity tended to be higher in less developed fruit at the lower pH of 6.0.

Catechol and chlorogenic acid showed reduced PPO activity compared with 4-methyl catechol over all development ages, however, there was a different pattern of response. Both catechol and chlorogenic acid showed greater PPO activity in the fully mature, day 92 fruit and less in the very young day 8 fruit, relative to the control 4-methyl catechol substrate. L-DOPA, as a substrate, showed a reaction lag as previously reported, and quite depressed PPO activity with no particular variation with development age compared to the control.

Pre-heating of fruit samples in air for 30 minutes resulted in increased inactivation with holding temperature (35°C - 31%, 45°C - 82%, 55°C - 97%, 65°C - 99%). Sulphite and NaCl acted as inhibitors with increasing effect as concentration increased. Added sulphite depressed PPO activity by about 30% at the level (2mM) used. This was less than the literature would suggest and it appeared that fully-ripe fruit were less inhibited than mature, non-ripe fruit. NaCl has a greater inhibitory effect on apricot PPO activity at the lower pH 5.0 tested. As NaCl added increases PPO activity decreases after an initial small rise. Again, less sensitivity to NaCl inhibition is shown by fruit of greater development age. Sensitivity to inhibition by SHAM, cinnamic acid and tropolone decreased with development age. Tropolone was the most effective inhibitor of apricot PPO.

The pattern of change in PPO activity, was consistent with physiological and biochemical changes reported by other workers as fruit develop from hard, green to soft, ripe. Regarding the existence of different PPO isozymes during development, no evidence of a isozyme based differential response with age was found within the constraints of the parameters tested.

Declaration

This thesis contains no material which has been accepted for an award of any degree or diploma in any University and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference is made in the text.

I give my consent to this copy of my thesis, when deposited in the University library, being available for loan and photocopying.

.....
R. B. Barrett, December, 2002

I, Andreas Klieber, consider that this thesis is, prima facia, worth examining for the award of Master of Applied Science (Agriculture).

Dr. A. Klieber Dated

Acknowledgements

My sincere appreciation goes to my supervisors, the late Dr Don Aspinall, Dr Simon Robinson and Dr Andreas Klieber for their excellent advice, patience and encouragement throughout this project and during the preparation of this thesis. In addition to my supervisors I would like to acknowledge the support of Dr John Jackson during the earlier stages prior to his retirement. Members of the Botany Department, particularly Professor Wiskich, Richard Norrish for electronic advice, Dr Ann Rathjen and Lidia Mischis for their valuable assistance and advice on the setting up of the Clark oxygen electrode. Biometrics SA staff member Helena Oakey was very helpful with statistical analysis and advice.

I wish to acknowledge gratefully the support of the University of Adelaide in providing a scholarship, which has enabled me to pursue the studies reported herein. The support of my colleagues within the Department of Horticulture, Viticulture and Oenology, particularly Professor Margaret Sedgley, has been appreciated for their continued encouragement.

Finally, I wish to express my appreciation to my wife, Angela, and to Samuel for grinding fruit, Daniel for computing and Michael for critical review. Thank you for your patience and encouragement throughout my studies.

Figure 3.3:	Adding extract to the reaction cell from chilled grinding mortar (Step 10).	59
Figure 3.4:	Adding 50 µl of 100 mM 4-Methyl Catechol substrate to Clark Electrode reaction cell containing apricot extract sample (PPO source) to initiate reaction (Step14).	59
Figure 3.5:	Sample output from the Clark oxygen electrode. Note the start point at the top is equivalent to 100% oxygen content in the reaction cell. The introduction of the 4-methyl catechol causes a "blip" (which may take a few seconds to stabilise). Slope of the initial reaction indicates PPO activity. These two samples show different initial reaction rates.	60
Figure 3.6:	Example output from the Clark oxygen electrode. In this example, following addition of substrate, there is a rapid development of a linear slope, which degrades into a slower rate curve associated with auto-inhibition. The straight line was used to show the slope of the initial reaction. At completion the slope levels out to an apparent 2-3% residual oxygen due to the electrode membrane characteristics. The vertical scale represents approx. 110% oxygen content down to approx. 10% (the plot is electrically offset to allow the recorder pen to accommodate the 'blip' associated with the addition of the substrate). Major horizontal scale is in centimeters, forward speed is 5cm min ⁻¹ .	61

Figure 6.1:	Structures of some phenolic substrates including D-L DOPA (centre), catechol (left) and chlorogenic acid [caffeoyl-quinic acid] (bottom left). Catechin (bottom right) is an example flavan-3-ol substrate type.	94
Figure 6.2:	Effect of the use of D-L DOPA as a substrate (2mM) on apricot (cv. Moorpark) PPO activity as a function of the maturity of the fruit from 'day' 1 (at capfall, approx. 5mm) to 92 days (over-ripe). PPO activity measured at 25°C in a Clark-type oxygen electrode, pH 6.8 buffer. PPO activity data are relative to the pH 6.8 standard using 4-methyl catechol as substrate, both at 2mM. Error bars are standard error of means (n=10).	95
Figure 6.3:	The effect of catechol as a substrate (2mM) on apricot (cv. Moorpark) PPO activity as a function of the maturity of the fruit from 'day1' (at capfall, approx. 5mm) to day92 (over-ripe). PPO activity measured at 25°C in a Clark-type oxygen electrode, pH 6.8 buffer using catechol as substrate, at 2mM. Error bars are standard error of means (n=10).	96
Figure 6.4:	Effect of the use of chlorogenic acid as a substrate (2mM) on apricot (cv. Moorpark) PPO activity as a function of the maturity of the fruit from 'day' 1 (at capfall, approx. 5mm) to 92 days (over-ripe). PPO activity measured at 25°C in a Clark-type oxygen electrode, pH 6.8 buffer. Figures of PPO activity are relative to the pH 6.8 standard using 4-methyl catechol as substrate, both at 2mM. Error bars are standard error of means, (n=10).	97
Figure 7.1:	Reaction lag output from the Clark oxygen electrode. Normally, following addition of substrate, there is a rapid development of a linear slope (left), which degrades into a slower rate curve associated with auto-inhibition. The straight line was used to show the slope of the initial reaction. When a lag occurs, as shown by the right hand slope line, a distinct delay occurs between adding the substrate and the beginning of oxygen use indicated by the sloping line. Lourenco <i>et al.</i> (1992) associated this lag with complexing of quinones with sulphite.	106
