I. INTRODUCTION

Voltage and ligand gated channels play an important role in initiating and modulating the subthreshold response and the action potential in nerve and muscle membranes [1]. For many years the dynamics of the transition between the closed and open states of voltage-dependent channels have been described by an empirical rate equation,

\[ \frac{dP_c(t)}{dt} = \alpha - (\alpha + \beta)P_c(t), \]

where \( \alpha \) and \( \beta \) are opening and closing transition rates and \( P_c(t) \) is the open state probability [2]. The dwell-time distribution for the open state of a nicotinic acetylcholine (nACh) ion channel is also an exponential function \( f_{\text{o}}(t) \) and is associated with the decay of the muscle endplate current [3]. If the ion channel sensor has multiple closed states and an open state, it is assumed that the dynamics of the system is described by a master equation. Although the discrete state Markov model has been successful in describing ionic and gating currents across the membrane, and closed and open dwell-time distributions in ion channels [1,4,5], it does not take account of the Brownian motion of large protein molecules in the energy landscape [6].

The open or closed state dwell-time distribution \( f(t) \) obtained from the patch clamp recording of stochastic current pulses in ion channels may be represented by a finite sum of exponential functions of time, and for several ion channels, \( f(t) \) may be approximated by a power law \( r^{-p-1} \) for intermediate times [7,8]. In order to account for multiple relaxation times and the emergence of a power-law approximation to the dwell-time distribution, both discrete [9–12] and continuous [13–16] diffusion models have been proposed, and if it is further assumed that there is an increasing barrier height and decreasing energy away from the open state, general power laws and a rate-amplitude correlation may be derived [17,18]. For a Ca-dependent K channel, the non-Markovian character of the current fluctuations and the dwell-time distribution power-law behavior [19,20] may be described by a fractional diffusion model of ion channel gating [21].

A numerical solution to a Smoluchowski equation for a voltage-dependent channel has shown that a large potential barrier between states ensures that the closed state is Markovian with a well-defined escape rate. The gating current has been computed for an energy landscape with potential barriers and a spatially inhomogeneous diffusion coefficient and is in qualitative agreement with experimental data [22].

The objective of the paper is to derive an analytical solution of the interacting Fokker-Planck equations for a closed region \( R_c \) and transition region \( R_m \) in response to a depolarizing voltage clamp, and to show that the solution has a single dominant relaxation time when \( D_m \sim D_c \) or the diffusion parameter \( \gamma_m \) is sufficiently large.

II. STOCHASTIC DIFFUSION MODEL OF ION CHANNEL GATING

The opening of ligand and voltage activated ion channels is dependent on the conformation of a sensor which is comprised of, in general, several macromolecules which may undergo rotation and translation between each surface of the membrane [1,23]. It is assumed that the sensor experiences Brownian motion in a closed state region \( R_c (x = \pm d_c) \), and a transition region \( R_m (0 \leq x \leq d_m) \), adjacent to the open state, with the dynamics described by the probability densities \( p_c(x,t) \) and \( p_m(x,t) \) which satisfy Fokker-Planck (or Smoluchowski) equations [24,25].

\[ \frac{\partial p_c(x,t)}{\partial t} = \frac{\partial}{\partial x} \left[ D_c(x) \frac{\partial p_c(x,t)}{\partial x} + \frac{\partial U_c(x)}{\partial x} p_c(x,t) \right], \]

\[ \frac{\partial p_m(x,t)}{\partial t} = \frac{\partial}{\partial x} \left[ D_m(x) \frac{\partial p_m(x,t)}{\partial x} + \frac{\partial U_m(x)}{\partial x} p_m(x,t) \right], \]

where \( U_c(x) \) and \( U_m(x) \) are potential functions. The diffusion coefficient \( D_c(x) = D_c \exp(\gamma_c x) \), \( D_m(x) = D_m \exp(-\gamma_m x) \), \( \gamma_c \) and \( \gamma_m \) are constants, and either \( D_c = D_m \) or there is a discontinuity at the interface between \( R_c \) and \( R_m \) (see Fig. 1).
dwell-time distribution is dependent on the variation in barrier height between closed states [18], and therefore we may consider the effect of the diffusion parameters \( D_m \) and \( \gamma_m \) in the transition region on the gating dynamics of an ion channel.

The diffusion in the region \( R_m \) is confined by the inner surface of the membrane, and therefore a reflecting boundary is imposed at \( x = -d_m \),

\[
\frac{\partial p_m(x,t)}{\partial x} + U'_c p_m(x,t) = 0, \tag{4}
\]

where \( \partial U_c(x) \partial x \) is assumed to be a constant \( U'_c \). Only unidirectional transitions from the closed to the open state are considered and therefore \( p_m(x_m, t) = 0 \). It may be assumed that the probability current and the probability density are continuous at the interface between \( R_m \) and \( R_c \),

\[
j_c(0, t) = j_m(0, t), \tag{5}
\]

\[
p_c(0, t) = p_m(0, t). \tag{6}
\]

The dwell time for each region is \( T_c = \int_{-d_c}^0 p_m(x, t) dx \) and \( T_m = \int_0^{d_m} p_m(x, t) dx \) where the survival probabilities \( P_m(t) = \int_{-d_c}^0 p_m(x, t) dx \) and \( P_m(0) = \int_0^{d_m} p_m(x, t) dx \) [5]. The ion channel is initially in a hyperpolarized state \( [P_c(0) = 1] \) and hence the initial condition may be specified as \( p_c(x, 0) = \delta(x) \) and \( p_m(x, 0) = 0 \), and we may assume that the ion channel is depolarized to a membrane clamp potential of \( V = V_f \) for which \( U_c(x) \) and \( U_m(x) \) are independent of \( x \).

The relative amplitude of the multiple relaxation times may be determined by solving Eqs. (2) and (3) with the initial and boundary conditions using the method of Laplace transforms. Defining \( z = z_0 \exp(-\gamma_0 x/2) \), \( z_d = z_0 \exp(\gamma_d x/2) \), \( y = y_0 \exp(\gamma_y x/2) \), \( y_d = y_0 \exp(\gamma_d x/2) \), \( p_c(x, t) = z u_c(z, t) \), and \( p_m(x, t) = y u_m(y, t) \), Eqs. (2) and (3) may be expressed as Bessel differential equations, and it may be shown that the probability that the sensor is in the region \( R_c \) and \( R_m \) is

\[
P_{c,m}(t) = \int_{-d_c}^{d_m} p(x, t) dx = \sum_{n=1}^{\infty} a_n \exp(-\omega_n t), \tag{7}
\]

where \( \omega_n = \mu_n^2 \), \( \mu_n ( < \mu_{sc} ) \) is a solution of the eigenvalue equation

\[
\frac{S_0(\mu_n, z_0, z_d) S_1(\mu_n, y_0, y_d)}{C_0(\mu_n, z_0, z_d) C_0(\mu_n, y_0, y_d)} = \sqrt{\frac{D_m}{D_c}}, \tag{8}
\]

and \( S_n(\mu_n, z_0, z_d) \) and \( S_n(\mu_n, y_0, y_d) \) for \( n = 0 \) or 1 are defined in terms of Bessel functions of the first and second kinds,

\[
C_0(\mu_n, z_1, z_2) = J_1(\mu_n z_1) Y_0(\mu_n z_2) - Y_1(\mu_n z_1) J_0(\mu_n z_2),
\]

\[
S_n(\mu_n, z_1, z_2) = J_1(\mu_n z_1) Y_n(\mu_n z_2) - Y_1(\mu_n z_1) J_n(\mu_n z_2),
\]

with similar definitions for the parameters \( y_1 \) and \( y_2 \),

\[
a_i = \frac{2 C_0(\mu_n, y_0, y_d)}{C_0(\mu_n, y_0, y_d)[h_1(\mu_n) + h_2(\mu_n) + h_3(\mu_n) + h_4(\mu_n)]},
\]

\[
h_1(\mu_n) = \frac{1}{S_0(\mu_n, z_0, z_d)} \left\{ \frac{d}{d\mu} [\mu S_0(\mu_n, z_0, z_d)] \right\},
\]

\[
h_2(\mu_n) = \frac{1}{S_1(\mu_n, y_0, y_d)} \left\{ \frac{d}{d\mu} [\mu S_1(\mu_n, y_0, y_d)] \right\},
\]

\[
h_3(\mu_n) = \frac{1}{C_0(\mu_n, z_0, z_d)} \left\{ \frac{d}{d\mu} [\mu C_0(\mu_n, z_0, z_d)] \right\},
\]

\[
h_4(\mu_n) = \frac{1}{C_0(\mu_n, y_0, y_d)} \left\{ \frac{d}{d\mu} [\mu C_0(\mu_n, y_0, y_d)] \right\}.
\]

Adopting a small argument approximation for the Bessel functions [26], from the solution (7)

\[
\frac{D_m}{y_m} = \frac{\exp(\gamma_m d_m) - 1}{T_c}. \tag{10}
\]

From Eqs. (7) and (8), if \( \gamma_m \) and \( \gamma_m \) are sufficiently small it may be shown that \( \omega_n \approx \frac{D_m}{d_m} \exp(\gamma_m d_m) \approx 1/T_c \) and

\[
\frac{1}{a_1} = \frac{1}{2} \sqrt{\frac{\tau_m/T_c}{1 + \tau_m \cos^2 \frac{\tau_m T_c}{2 T_c} + \frac{\tau_m T_c}{2 T_c} + \frac{\tau_m}{T_c}}}, \tag{11}
\]

where \( \tau_m = d_m^2 / D_m \) and \( \tau_c = d_c^2 / D_c \). Therefore \( P_m(t) \) may be approximated by the lowest frequency component with opening rate \( \alpha \approx 1/T_c \) when \( \tau_c \ll T_c \) and \( \tau_m \ll T_c \) or equivalently

\[
\frac{D_m}{D_c} \approx \frac{d_m}{d_c} \ll 1, \tag{12}
\]

and is in good agreement with the survival probability of the slow closed state for a delayed rectifier K channel, after eliminating the fast closed component with a low frequency filter [27] (see Fig. 2). The relation \( d_m \ll d_c \) may be obtained from the voltage dependence of the mean closed time for an interacting diffusion regime [15] or from the requirement that the probability current in the transition region is quasistationary [18], and \( \tau_m \ll T_c \) is also satisfied when there is a large potential barrier in the region \( R_m \). A short time after the application of the voltage clamp, the spatial variation of the probability density \( p(x, t) \) is approximately linear in the region \( R_m \) (see Fig. 3) and therefore the probability current is constant within the transition region.
FIG. 2. The survival probability of the slow closed state for a delayed rectifier K channel [27] (dotted line) and the analytical solution \( P_{cm}(t) \) (solid line) where \( d_m/d_c = 0.15, D_m/D_c = 0.0225, \tau_c = 3.4 \text{ ms}, \gamma_c, \gamma_m \rightarrow 0, a_i = (0.977, 0.130, -0.103, \ldots) \), and \( \omega_i = (0.040, 2.26, 3.62, \ldots) \).

By assuming that \( D_i(x) = D_m(x) = D \) and \( d_m \ll d_c \), it follows that \( T_c = \tau_c d_m/d_c \ll \tau_c \), and the dwell-time distribution for intermediate times may be described by a power law (see Fig. 4) [9,11,15], as observed in several types of ion channels for the closed states accessible from the open state during a depolarizing voltage clamp. However, it should be noted that the closed states associated with a power-law approximation to the dwell-time distribution are, generally, not the same as those in the activation sequence [28].

If \( D_i(x) = D_c, \gamma d_i \ll 1, \) and \( \gamma d_m \gg 1 \), adopting a small argument approximation in \( R_m \) and large argument approximation in \( R_c \) [26], it may be shown from Eqs. (7) and (8) that

\[
\frac{1}{\omega_1} \approx \frac{d_c \exp(\gamma_m d_m) - 1}{D_m \gamma_m} \approx T_c, \tag{13}
\]

and thus \( a_1 = 1 \) and \( a_i = 0 \) for \( i > 1 \) when

\[
\frac{\gamma_m d_m}{\exp(\gamma_m d_m) - 1} \ll \frac{d_m}{d_c}, \tag{15}
\]

and

\[
\frac{1}{a_i} \approx 1 + \frac{\gamma d_c}{2 \exp(\gamma_m d_m) - 1}. \tag{14}
\]

Thus, \( a_i \approx 1 \) and \( a_i \approx 0 \) for \( i > 1 \) when

or from Eq. (10), \( \tau_c \ll T_c \). Therefore, when \( \gamma_m \) is sufficiently large, \( P_{cm}(t) = \exp(-\omega_1 t) \), and in agreement with the data from a delayed rectifier channel [27] (see Fig. 5).

III. DISCUSSION

Gating in voltage or ligand activated ion channels is regulated, in general, by several macromolecules which experience Brownian motion in the closed and open regions, where the dynamics may be described by probability densities which satisfy interacting Fokker-Planck equations. We have shown that a single dominant relaxation time may be derived from a position-dependent stochastic diffusion model when there is a discontinuity in the diffusion coefficient at the between the regions \( R_m \) and \( R_c \), with \( D_m \ll D_c \), and the width of the transition region \( (d_m) \) is much less than the width of the closed region \( (d_c) \). These conditions ensure that \( \tau_c \ll T_c \) and \( \tau_m \ll T_m \), and therefore the Brownian motion in the closed and transition regions may be described as quasistationary. The small relative value of \( d_m \) is consistent with recent experimental data that indicate that each S4 sensor has a translation of the order of 6 Å across a focused electric field [29]. If \( D_m(x) = D_m \exp(-\gamma_m x) \), the response of the system to a depolarizing voltage clamp may also be approximated by the lowest frequency relaxation when the diffusion parameter \( \gamma_m \) is sufficiently large.

FIG. 3. The probability density \( p(x,t) \) in the region \( R_c (-d_c \leq x < 0) \) and \( R_m (0 \leq x \leq d_m) \) for \( t_1 = 2 \text{ ms} \) (solid line) and \( t_2 = 20 \text{ ms} \) (dotted line) where \( d_m/d_c = 0.15, D_m/D_c = 0.0225, \tau_c = 3.4 \text{ ms}, \gamma_c, \gamma_m \rightarrow 0 \).

FIG. 4. The survival probability \( P_{cm}(t) \) (solid line) and the lowest frequency component \( a_1 \exp(-\omega_1 t) \) (dotted line) where \( d_m/d_c = 0.15, D_c = D_m, T_c = 24 \text{ ms}, \gamma_c, \gamma_m \rightarrow 0, a_i = (0.259, 0.245, 0.218, \ldots) \), and \( \omega_i = (0.012, 0.105, 0.292, \ldots) \).

FIG. 5. The survival probability of the slow closed state for a delayed rectifier K channel [27] (dotted line) and the analytical solution \( P_{cm}(t) \) (solid line) where \( d_m/d_c = 0.15, \tau_c = 0, \gamma_m d_m = 6, \tau_c = 2.2 \text{ ms}, a_i = (0.984, 0.055, -0.030, \ldots) \), and \( \omega_i = (0.04, 3.5, 7.48, \ldots) \).
If the opening of the ion channel is determined by m identical and independent subunits and the conductance of the channel is expressed as $g = \frac{P_0(t)}{e}$ [2], a rate equation may be derived for each subunit when there is a large diffusion or potential barrier between the closed and open configurations of each sensor molecule. When the closed state dwell-time distribution obtained from a patch clamp recording has a finite number of relaxation times, the closed states may be represented as energy wells between potential or diffusion barriers within an energy landscape, and the resulting system of interacting Fokker-Planck equations may be approximated by a Markovian master equation.
