Abstract

It is well established that stock market volatility has a memory of the past, moreover it is found that volatility correlations are long ranged. As a consequence, volatility cannot be characterized by a single correlation time in general. Recent empirical work suggests that the volatility correlation functions of various assets actually decay as a power law. Moreover it is well established that the distribution functions for the returns do not obey a Gaussian distribution, but follow more the type of distributions that incorporate what are commonly known as \textit{fat–tailed} distributions. As a result, if one is to model the evolution of the stock price, stock market or any financial derivative, then standard Brownian motion models are inaccurate. One must take into account the results obtained from empirical studies and work with models that include realistic features observed on the market.

In this thesis we show that it is possible to derive the path integral for a non-Gaussian option pricing model that can capture fat–tails. However we find that the path integral technique can only be used on a very small set of problems, as a number of situations of interest are shown to be intractable.
Statement of Originality

This work contains no material that has been accepted for the award of any other degree or diploma in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text.

I give consent to this copy of the thesis, when deposited in the University Library, being available for loan, photocopying, and dissemination through the library digital thesis collection, subject to the provisions of the Copyright Act 1968. Copying or publication or use of this thesis or parts thereof for financial gain is not allowed without the authors written permission. Due recognition shall be given the author, and the University of Adelaide, in any scholarly use that may be made of any material in the thesis.

Acknowledgments

I would like to acknowledge the support that my supervisors have given me along the course of the program. In particular I would like to thank Professor Derek Abbott for all the financial support that he has provided me along the years that I have been part of the Electrical and Electronic Engineering school. I would like to also take the opportunity to thank Andrew Allison for taking the time to listen and for all of his constructive comments. Furthermore I would like to thank John van der Hoeck for all the support he has given me with some of the mathematical aspects.

A special thanks to my family members without whom things would not have been possible.

I would like acknowledge the School of Electrical and Electronic Engineering and the Australian Research Council for their financial support. I also acknowledge the SPIE travel grant that covered some of the travel expenses.

Special thanks to Carl Chiarella (University of Technology of Sydney), Lisa Borland (Evnine-Vaughan Associates), Jean-Philippe Bouchaud (Capital Fund Management), Didier Sornette (Université Nice Sophia–Antipolis) who kindly hosted my short visits to their research labs.

I would also like to take the opportunity to thank some of the researchers who patiently took some of their time to listen through some of the technical discussions, and for useful and stimulating discussions, these include Robert Elliot (University of Calgary), Dominique Guegan (Université Panthéon-Sorbonne), and Peter Hänggi (Universität Augsburg). Also acknowledged is Michel M. Dacorogna for finding the paper on the origin of the term martingale (Mansuy 2005).

Finally I would like to thank Professor Bevan Bates for his constructive advice and support. I would like to thank the research committee as a whole for their help and advice.

At last I would like to thank Rose-Marie for organizing the weekly lunch meetings, which provided nice lunch breaks.
Conventions and formsetting

0.1 Typesetting

This thesis is typeset using the \LaTeX\ Xe software. WinEdt build 5.4 was used as an effective interface to \LaTeX\ (Oetiker et al. 2000). Harvard style is used for referencing and citation in this thesis. Australian English spelling is adopted, as defined by the Macquarie English Dictionary (Delbridge 2001).

0.2 Software

The results were obtained using mathematical packages (Mathematica, Matlab), statistical packages (R).

The programming language used was Fortran 90 with parallel commands embedded in it. Also used was C++.

The reason being that it is more realistic in our days to have a wide range of computer skills instead of just a highly specialized one which may not be compatible elsewhere.

0.3 Data

The data was obtained from two different sources

- The yahoo finance website (Yahoo Finance 2008).
- The Tick Data website (Tick Data Global Historical Data Solutions 2008).
