Investigation of Single and Multiple Faults Under Varying Load Conditions Using Multiple Sensor Types to Improve Condition Monitoring of Induction Machines

PhD Thesis

Intesar Ahmed

A Thesis Presented for the Degree of Doctor of Philosophy

September 2007
Abstract

Condition monitoring involves taking measurements on an induction motor while it is operating in order to detect faults. For this purpose normally a single sensor type, for example current is used to detect broken rotor bar using fault frequency components only under the full-load condition or a limited number of load cases. The correlations among the different types of sensors and their ability to diagnose single and multiple faults over a wide range of loads have not been the focused in previous research.

Furthermore, to detect different faults in machines using any fault frequency components, it is important to investigate the variability in its amplitude to other effects apart from fault severity and load. This area has also often been neglected in the literature on condition monitoring.

The stator current and axial flux have been widely used as suitable sensors for detecting different faults i.e. broken rotor bar and eccentricity faults in motors. Apart from detecting the broken rotor bar faults in generalized form, the use of instantaneous power signal has often been neglected in the literature condition monitoring.

This thesis aims to improve machine condition monitoring and includes accurate and reliable detection of single and multiple faults (faults in the presence of other faults) in induction machines over a wide range of loads of rated output by using current, flux and instantaneous power as the best diagnostic medium.

The research presents the following specific tasks:

A comprehensive real database from non–invasive sensor measurements, i.e. vibration measurements, axial flux, 3-phase voltage, 3-phase current and speed measurements of induction motor is obtained by using laboratory testing on a large set of identical motors with different single and multiple faults. Means for introducing these faults of varying severity have been developed for this study.

The collected data from the studied machines has been analysed using a custom-written analysis programme to detect the severity of different faults in the machines. This helps to improve the accuracy and reliability in detecting of single and multiple faults in motors using fault frequency components from current, axial flux and instantaneous power spectra.
This research emphasises the importance of instantaneous power as a medium of detecting different single and multiple faults in induction motor under varying load conditions. This enables the possibility of obtaining accurate and reliable diagnostic medium to detect different faults existing in machines, which is vital in providing a new direction for future studies into condition monitoring.

Another feature of this report is to check the variability in healthy motors due to: test repeatability, difference between nominally identical motors, and differences between the phases of the same motor. This has been achieved by conducting extensive series of laboratory tests to examine fault frequency amplitudes versus fault severity, load, and other factors such as test repeatability and machine phases.

The information about the variations in the amplitudes of the fault frequency components is used to check the accuracy and reliability of the experimental set-up, which is necessary for the practical application of the results to reliably detect the different faults in the machines reliably.

Finally, this study also considers the detection of eccentricity faults using fault frequency amplitudes as a function of average eccentricity, instead of as a function of load under different levels of loading. This has not been reported in previous studies.
Declaration

This work contains no material which has been accepted for the award of any other degree or diploma in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text.

I give consent to this copy of my thesis, when deposited in University Library, being made available for photocopy and loan subject to the provisions of the Copyright Act 1968

Acknowledgment

The research work and the experimental work related to this project were carried out at the Power Engineering Laboratory at the School of Electrical and Electronics Engineering, University of Adelaide, Adelaide, South Australia.

Associate Professor Nesimi Ertugrul has acted as a supervisor and I gratefully acknowledge his valuable advice, guidance, and encouragement during the study and also for his positive attitude to my work. I also highly acknowledged the valuable advice from Dr. W. L. Soong during my study.

I am thankful to all technical staff of Power Engineering Laboratory for providing the experimental needs and technical assistance throughout the study. My thanks are also due to all academic and administration staff members for creating a best environment for study.

Special thanks to my wife “Farhat Sultana” for her positive attitude and taking care of children’s during study. I deeply appreciate my father Dr. Zaki Ahmad for his encouragement, economical support and looking after my family.

Figure 6.8: Comparison of variations in flux sideband amplitudes for three tests on the same healthy motor. The faulty motor result is shown for reference. ..........113

Figure 6.9: Variations in shorted turn sideband amplitudes for tests on two nominal identical healthy motors. The result of faulty motor is shown for reference. ......................................................................................................................114

Figure 6.10 Variations in shorted turn sideband amplitudes for tests on two nominal identical healthy motors. Faulty motor result is shown for reference........114

Figure 6.11: Comparison of the instantaneous power spectrum from a healthy motor at 30% load (top row) and at full-load (bottom row)..............................................115

Figure 6.12: Variations in the shorted turn sidebands amplitudes versus % of rated load of healthy motor for different values of k from instantaneous power spectrum. ..........................................................................................................116

Figure 6.13: Variations in shorted turn sideband amplitudes for three tests on the same healthy motor at full-load.............................................................................117

Figure 6.14: Variations in the shorted turn sideband amplitudes for tests on two identical healthy motors at 100% load.................................................................118

Figure 6.15: Variations in shorted turn sideband amplitudes of the healthy and faulty motor between phases A and B at full-load..................................................118

Figure 6.16: Variations in the sideband amplitudes for the healthy and faulty motor (with 20 shorted turns). Top row (left) and top row (right) show the flux and instantaneous power. The Bottom (row) represents a single signal.............120

Figure 7.1: schematic diagram of parallel and angular misalignment.................................123

Figure 7.2: Comparison of the current, flux and instantaneous power spectrums from a healthy machine with a misaligned machine showed in (top, middle and bottom row) at full-load. .................................................................124

Figure 7.3: Comparison of variation in sideband amplitudes versus % of rated load of a healthy motor with misaligned motor from current spectrum. ..................125
Figure 7.4: Comparison of variation in sideband amplitudes versus % of rated load of a healthy motor with misaligned motor from flux spectrum. ..........................126

Figure 7.5: Comparison of variation in sideband amplitudes versus % of rated load of a healthy motor with misaligned motor from instantaneous power spectrum. ......................................................................................................................126

Figure 7.6: Current spectrum from a healthy machine (top row) and a misaligned machine (bottom row) at full-load. ..............................................................127

Figure 7.7: Flux spectrum from a healthy machine (top row) and a misaligned machine (bottom row) at full-load. ..............................................................128

Figure 7.8: Instantaneous power spectrum from a healthy machine (top row) and a misaligned machine (bottom row) at full-load. ..............................................................128

Figure 7.9: Comparison of variations in sideband amplitudes versus % of rated load of healthy motor with misaligned motor from current spectrum. ..................129

Figure 7.10: Comparison of variations in sideband amplitudes versus % of rated load of healthy motor with misaligned motor from flux spectrum. ..................130

Figure 7.11: Comparison of variations in sideband amplitudes versus % of rated load of healthy motor with misaligned motor from instantaneous power spectrum. ......................................................................................................................130

Figure 7.12: Current spectrum from a healthy machine (top row) and a misaligned machine (bottom row) at full-load. ..............................................................131

Figure 7.13: Flux spectrum from a healthy machine (top row) and a misaligned machine (bottom row) at full-load. ..............................................................132

Figure 7.14: Instantaneous power spectrum from a healthy machine (top row) and a misaligned machine (bottom row) at full-load. ..............................................................132

Figure 7.15: Comparison of variations in sideband amplitudes versus % of rated load of healthy motor with misaligned motor from current spectrum. ..................133

Figure 7.16: Comparison of variations in sideband amplitudes versus % of rated load of healthy motor with misaligned motor from flux spectrum. ..................134
Figure 7.17: Comparison of variations in sideband amplitudes versus % of rated load of healthy motor with misaligned motor from instantaneous power spectrum. .................................................................134

Figure 8.1: Flux spectrum of slip frequency versus sidebands amplitudes under different level of load tests..................................................................................................................137

Figure 8.2: Current spectrum from a healthy machine (left) and a faulty machine with two broken rotor bars and eccentricity of +0.3mm at driving-end (right), at no-load, 50% load and full-load. The circles indicate the sidebands............138

Figure 8.3: Comparison of variation in sidebands amplitudes versus % of rated load of a healthy motor with faulty motors (combination of two broken bars and eccentricity of +0.1mm and +0.3 mm at driving-end) from current spectrum. ......................................................................................................................139

Figure 8.4: Flux spectrum from a healthy machine (left) and a faulty machine with two broken rotor bars and eccentricity of +0.3mm at driving-end (right), at no-load, 50% load and full-load. The circles indicate the sidebands. .............140

Figure 8.5: Comparison of variation in sidebands amplitudes versus % of rated load of a healthy motor with faulty motors (combination of two broken bars and eccentricity of +0.1mm and +0.3 mm at driving-end) from flux spectrum. 141

Figure 8.6: Instantaneous power spectrum from a healthy machine (left) and a faulty machine with two broken rotor bars and eccentricity of +0.3mm at driving-end (right), at no-load, 50% load and full-load. The circles indicate the sidebands. ..............................................................................................................142

Figure 8.7: Comparison of variation in sidebands of a healthy motor with faulty motors (combination of two broken bars and eccentricity of +0.1mm and +0.3 mm at driving-end) from instantaneous power spectrum. ..............................................143

Figure 8.8: Current spectrum from a healthy motor (top) and a faulty motor with eccentricity of +0.3 mm at driving-end (bottom) at 30% load. The circles indicate the sidebands. .................................................................145
Figure 8.9: Current spectrum from a healthy motor (top) and a faulty motor with eccentricity of +0.3 mm at driving-end (bottom) at full-load. The circles indicate the sidebands. ................................................................. 146

Figure 8.10: Comparison of variation in sidebands amplitudes versus % of rated load of a healthy motor with faulty motors (combination of two broken bars and eccentricity of +0.1mm and +0.3 mm at driving-end) from current spectrum. .................................................................................................................. 147

Figure 8.11: Flux spectrum from a healthy motor (row 1 and 3) and a faulty motor with eccentricity of +0.3 mm at driving-end (row 2 and 4) at 30% load and full-load. The circles indicate the sidebands........................................ 148

Figure 8.12: Comparison of variation in sidebands amplitudes versus % of rated load of a healthy motor with faulty motors (multiple faults) from flux spectrum. ..... 149

Figure 8.13: Instantaneous power spectrum from a healthy motor (row 1 and 3) and a faulty motor (row 2 and 4) at 30% load and full-load respectively. .............. 150

Figure 8.14: Comparison of variation in sidebands amplitudes of a healthy motor with faulty motors (combination of two broken bars and eccentricity of +0.1mm and +0.3 mm at driving-end) from instantaneous power spectrum. .......... 151
List of Tables

Table 3.1: Technical information for the induction motors used in the testing.................48
Table 3.2: Technical information about the DC machine used in the testing .................49
Table 3.3: Alignment limits and the actual measured values obtained for a test motor...50
Table 3.4: Sensor specifications .......................................................................................52
Table 3.5: Summary of sensor signal sampling information........................................53
Table 4.1: Summary of fault frequencies associated with different types of faults. .........60
Table 4.2: Comparison of healthy and faulty motors results to detect the broken rotor bar faults using current, flux and instantaneous power spectra. .........................76
Table 5.1: Different combinations of airgap eccentricity developed in the machine to study the severity of eccentricity faults under different loading conditions. ....79
Table 5.2: Comparison of healthy and faulty motors for detecting eccentricity faults using components \(f_1 \pm f_r\) under different levels of loading. The average eccentricity level is considered from 0 to 0.3 mm at the non-driving-end. 104
Table 5.3: Comparison of healthy and faulty motors to detect the eccentricity faults using components \(f_1[(R/p)(1-s)\pm k]\) under different levels of loading. Eccentricity level is +0.3 mm at non-driving-end ..........................................................105
Table 6.1: Number of turns short-circuiting to investigate the severity of shorted turns fault versus % of rated loads. ........................................................................107
Table 6.2: Comparison of healthy and faulty motors in detecting shorted turn faults using components \(f_1[(n/p)(1-s)\pm k]\) under different levels of loading. .........................121
Table 8.1: Comparison of healthy and faulty motors to detect the multiple faults in the presence of eccentricity level of 0.3 mm using BRB components \((1\pm 2s)f_1\). 144
Table 8.2: Comparison of healthy and faulty motors to detect the multiple faults in the presence of broken rotor bars using \((f_1 \pm f_r)\). ..........................................................152
