List of Figures ......................................................................................... iv  
List of Tables .......................................................................................... ix  
Acknowledgements ................................................................................... xiii  
Abstract .................................................................................................... xiv  
Declaration .................................................................................................. xvi  
Chapter 1: Introduction ............................................................................... 1  
Chapter 2: Literature Review .................................................................... 3  
  2.1 CCA Timber Treatment ....................................................................... 3  
  2.2 The CCA Disposal Problem .................................................................. 8  
  2.3 CCA Disposal Options ......................................................................... 13  
  2.4 Wood Pulping ...................................................................................... 18  
  2.5 Conclusions ......................................................................................... 21  
Chapter 3: Materials and Methods ............................................................... 23  
  3.0 General Materials and Methods information ........................................ 23  
  3.1 Initial Nitric Acid Extraction Experiment ............................................. 24  
  3.2 Determining the Effect of Acid Concentration, Temperature, and Particle Size on CCA Extraction ................................................................. 26  
  3.3 Soaking of Sawdust and Wood Cubes at Room Temperature in Water and Nitric Acid ................................................................. 32  
  3.4 Nitric Acid Extraction of CCA Wood Chips ......................................... 33  
  3.5 Long-term Soaking of CCA Logs in Water at Room Temperature ........ 38  
  3.6 CCA Variation With Depth in a New Post ........................................... 40  
  3.7 CCA Variation With Depth in Aged Posts ........................................... 42  
  3.8 CCA Distribution with Depth at Low-Resolution ............................... 44  
Chapter 4: Results and Discussion ............................................................... 47  
  4.1 Initial Nitric Acid Extraction Experiment ........................................... 49  
  4.2 Determining the Effect of Acid Concentration, Temperature and Particle Size on CCA Extraction ................................................................. 51  
  4.3 Soaking of Sawdust and Wood Cubes at Room Temperature in Water and Nitric Acid ................................................................. 62
Table of Contents

4.4 Nitric Acid Extraction of CCA Wood Chips .......................................................... 69
4.5 Long-term Soaking of CCA Logs in Water at Room Temperature .................... 75
4.6 CCA Variation With Depth in a New Post.......................................................... 79
4.7 CCA Variation with Depth in Aged Posts......................................................... 81
4.8 CCA Variation with Depth at Low-Resolution ................................................. 92

Chapter 5: Conclusions and Recommendations ...................................................... 108

Appendix A: Method for complete extraction of Copper, Chromium and Arsenic from pressure treated wood ........................................................................................................ 115

Appendix B: Preparation of samples for ICPMS analysis ........................................ 116

Appendix C: Copper Chrome Arsenate (CCA) Formulations currently registered in Australia ........................................................................................................ 118

Appendix D: Error Analysis ..................................................................................... 120

Appendix E: Estimation of Evaporation Rates for Experiment 3.2 ......................... 122

Appendix F: Results from Experiment 3.2 .............................................................. 125

F.1: Experiment 1: Sawdust in 5% nitric acid at 50°C ........................................... 126
F.2: Experiment 2: 10mm wood cubes in 5% nitric acid at 50°C ......................... 128
F.3: Experiment 3: 5mm wood cubes in 10% nitric acid at 50°C ......................... 130
F.4: Sawdust in 15% nitric acid at 50°C (experiment 4) ..................................... 132
F.5: 10mm wood cubes in 15% nitric acid at 50°C (experiment 5) .................... 134
F.6: 5mm wood cube in 5% nitric acid at 70°C (experiment 6) ......................... 136
F.7: Sawdust in 10% nitric acid at 70°C (experiment 7) ...................................... 138
F.8: 5mm cubes in 10% nitric acid at 70°C (experiment 8) .............................. 140
F.9: 5mm cubes in 10% nitric acid at 70°C (repeat) (experiment 9) ................. 142
F.10: 5mm cubes in 10% nitric acid at 70°C (experiment 9 and 10 data combined) .............................................................................................. 144
F.11: 10mm cubes in 10% nitric acid at 70°C (experiment 10) ......................... 146
F.12: 5mm cubes in 15% nitric acid at 70°C (experiment 11) ......................... 148
F.13: Sawdust in 5% nitric acid at 90°C (experiment 12) .................................... 150
F.14: 10mm wood cubes in 5% nitric acid at 90°C (experiment 13) ................. 152
F.15: 5mm wood cubes in 10% nitric acid at 90°C (experiment 14) ................. 154
Table of Contents

F.16: Sawdust in 15% nitric acid at 90°C (experiment 15) ........................................ 156
F.17: 10mm wood cubes in 15% nitric acid at 90°C (experiment 16) ..................... 158

**Appendix G: Results from experiment 3.4** ......................................................... 160
G.1: Extraction from New Post (NEW 4) ................................................................. 160
G.2: Extraction from New Post (NEW 4) – repeat ............................................... 162
G.3: Extraction from 11 year old post (above ground) ........................................ 164
G.4: Extraction from 11 year old post (below ground) ........................................ 166
G.5: Extraction from 17 year old post (above ground) ....................................... 168
G.6: Extraction from 17 year old post (below ground) ....................................... 170
G.7: Extraction from 33 year old post (above ground) ...................................... 172
G.8: Extraction from 33 year old post (above ground - repeat) ......................... 174
G.9: Extraction from 33 year old post (ground level) ....................................... 176
G.10: Extraction from 41 year old post (above ground) .................................... 178
G.11: Extraction from 41 year old post (above ground - repeat) ....................... 180

**Appendix H: Order of Magnitude Cost Estimation** ............................................ 182

**Appendix I: CCA Impregnation Process** ......................................................... 188

**References** ...................................................................................................... 191

Acknowledgements

I am indebted to many people for vital support and advice through the course of this study. First and foremost, my principal supervisor associate professor Brian O’Neill for his patience and advice, both personal and professional. Without his assistance I would never have been able to complete this study. Further, I wish to thank my initial supervisor Dr Chris Colby. Brian and Chris made me aware of the CCA problem and gave me the freedom to approach it how I saw fit.

The support staff in the School of Chemical Engineering have also been amazing in the help they provided me. Laboratory managers Andrew Wright and Leanne Biddis were fantastic in their support and advice, giving me the time and space needed to run my various experiments. The Chemical Engineering workshop employees Jason Peak, Michael Jung and Jeffrey Hiorns who helped with construction of my experimental rig and access to all their wood cutting equipment. I want to especially thank Jeffrey for patiently cutting up thousands of tiny wood cubes for my experiments. Finally, the school secretaries, Mary Barrow and Elaine Minerds, whose help in administration have been vital in my time here.

I wish to thank Associate Professor Peter Ashman from the School of Chemical Engineering for access to his grinding equipment, despite me not being one of his students.

The School of Chemistry and Physics was fantastic in the support and advice they gave me, despite not being one of their students. Gino Ferese gave me time to use their fume cupboards, despite me accidentally flooding the lab, and Hugh Harris gave me excellent advice and time when I was attempting to gain access to the Australian Synchrotron.

Dr Benjamin Wade and Mr Angus Netting from Adelaide Microscopy were vital in their advice and assistance in preparation and analysis of all my samples.

Industry advice from Dr Harry Greaves, Mr Chris Titilaris and Mr John Blumson were crucial in my understanding of the nature of CCA wood treatment and disposal.

I wish to of course thank my family and friends, whose support and advice have kept me going. Their encouragement was vital.

And finally, I am most indebted to the personal support of my amazing wife, Helena Wood. She is the most important person in my life.
Abstract

Treated timber is a widely used construction material, as it is resistant to insect and fungal attack. The most commonly used timber treatment solution worldwide is copper chromium arsenate (CCA) pressure treated wood (APVMA 2005a). Environmental and health issues have been raised over CCA wood, with major particular concern raised on the possibilities of arsenic in the wood potentially leaching out. The Australian Pesticides and Veterinary Medicines Authority (APVMA) have limited its usage to minimise human contact with CCA structures (APVMA 2005a). In South Australia, CCA applications increased dramatically with the expansion of the winery industry where CCA treated timber posts were widely used for vineyard trellises. Due to the mechanical method by which most grapes are harvested, roughly 2% of all posts are broken and require disposal annually (SAEPA 2008). The Environmental Protection Agency of South Australia (EPASA) have placed restrictions on CCA disposal from vineyards (SAEPA 2004) and waste CCA stock is either stockpiled or sent to specially lined landfills incurring an estimated cost penalty of over $AU 200 per tonne\(^1\). Clearly, improved CCA treatment technologies must be developed to reduce (or eliminate) the cost of CCA disposal and to the footprint of land filled waste.

CCA timber disposal techniques currently being researched are focussed primarily on thermal and biological routes. Thermal techniques are problematic due to volatilization of the arsenic in the product, whilst biological removal techniques are very slow. Chemical remediation is an alternative and attractive disposal technique of interest using various acids to extract copper, chromium and arsenic. Nitric acid has been shown to be particularly effective (Honda, Kanjo et al. 1991), although research has been limited. Nitric acid is also used in one method of paper pulp production, and as such, there is the potential for a combined CCA extraction and paper pulp process. This has the attraction of turning a waste in a value added product.

The kinetics of copper, chromium and arsenic dissolution in nitric acid has been examined in this thesis. A key finding of the work identifies the size of CCA wood particles as the dominant factor affecting the extraction rate, whilst temperature and acid concentration only provide a minor effect. The extraction rate for all elements from CCA wood using nitric acid generally follow 2\(^{nd}\) order kinetics. Concurrently, a study examining wood chips of various ages taken from vineyards was performed using chip sizes typical required for paper production. It was found that despite significant variations in the concentration profile of CCA in posts, a general model based on the fraction of each element

could be created for posts of all ages. Over an 8 hour period, 65-80% of chromium, 50-70% of copper and 75-90% of arsenic was extracted from all posts.

Given the excellent extraction observed under relatively simple nitric acid extraction, further studies on the applicability of nitric pulping for CCA remediation are recommended. Minimizing chip size subject to fibre size constraints in paper production is key to improved removal and additional means for enhancing chip surface area are identified. Other stages present in paper pulping process may solublize additional CCA and these warrant further investigation. A basic economic estimation was undertaken, where it was found that creating paper pulp from CCA wood could be economically feasible, but will require further research to determine the expected costs and revenues involved.

The nature of the CCA wood waste was investigated. The expectation was that CCA posts would contain relatively consistent concentration profiles for copper, chromium and arsenic. However, it was observed that the concentrations were quite varied. Further, several posts produced during the wine boom in South Australia were very poorly treated with very poor penetration of the preservatives into the posts. This could result in a reduced lifetime for the posts, and potentially higher arsenic leaching than expected. It is also recommended that the frequency of these poorly treated posts be determined, as three of the six posts examined from this period were potentially poorly treated, implying it may be significant and unexpected problem. In addition, a study should be initiated to determine if these poorly treated posts are leaching higher levels of arsenic, by both a study of the surrounding soil and a simulated rainfall leaching experiment.

Based on the concern that more arsenic leached from pieces of CCA post left in deionised water than expected, an experiment on posts of various ages revealed that over a 100 day period, 1.5-3g of elemental arsenic could leach from a submerged CCA treated post. There is a serious concern that with CCA posts being landfilled, they will be exposed to water contact over the wet months, resulting in high arsenic leaching. It is theorised that this high arsenic leaching is due to insufficient chromium in the CCA solution. Previous studies have recommended higher chromium to arsenic ratios than are currently employed in Australia. Further studies on the extent to which this leaching can occur in landfill are recommended.
