| Title: | Pharmacological management of low milk supply with domperidone: separating fact from fiction - Letter |

**Abstract**

Articles requiring a descriptive 15-word introductory line are: Editorials, and Perspectives.

Articles requiring short (50-word) unstructured abstracts are: Notable cases (abstract should state the general area of relevance, describe the specific nature of the case, and point out the relevance/implications for clinical practice or health policy).

Articles requiring 4–6 bullet-point) summaries are: Clinical focus article including narrative review.

Articles requiring structured abstracts are:

- **Research reports** (use the headings: Objectives, Design, Setting, Participants, Main outcome measures, Results, Conclusions and Trial registration [if applicable]) and
- **Systematic reviews** (use the headings: Objective, Study design, Data sources, Study selection, Data extraction, Data synthesis, Conclusions).

| Abstract word count | N/A |

No Abstract Required

See over
Research reports should be written in IMRAD format (Introduction, Methods, Results and Discussion).
Case reports should comprise a Clinical record followed by a Discussion.

Following the publication of our peer-reviewed perspective article on the safe and effective use of domperidone in the management of low milk supply,¹ we are disappointed to have been informed that the Australian Medicines Handbook (AMH) has made the decision to remove lactation stimulation as a recognised off-label indication for domperidone (as well as metoclopramide). It appears that this change could be a kneejerk response to recent regulatory warnings, despite these being highlighted as not being of relevance to the vast majority of breastfeeding women.¹ ² These changes carry with them the significant potential to create confusion amongst prescribers and the public.

We would like to re-emphasise previous points that further restrictions regarding the use and availability of domperidone do not appear warranted and risk subjecting women to additional emotional trauma and are not in the interests of the immediate and long-term health of breastfeeding women and their babies.¹ ² There is absolutely no evidence that domperidone places breastfeeding mothers at increased risk of severe cardiac events, whereas in contrast, there is evidence of the significant benefits to be gained from the use of domperidone in supporting breastfeeding.
Domperidone has been used widely in clinical practice for women experiencing low milk supply,³ with no reports of significant adverse effects.

Ultimately, the resultant change in the recommendations for domperidone use by the AMH could be considered a form of restriction and risk women receiving substandard clinical care. That said, we re-emphasise our previous practice points regarding the importance of adequately screening women for factors that may place them at increased risk of cardiac arrhythmia should this be of concern.

It is clear that domperidone is not a magic bullet for adequate milk production in breastfeeding women. Non-pharmacological management options are the mainstay of treatment, with medications only to be considered as a last line of resort, and always in addition to these management strategies.⁴ There is no
easy fix when it comes to supporting women who are struggling with low milk supply but when used appropriately, domperidone can be a very safe and effective treatment option.
